Highlights

- We provide a Predictive Processing formalization based on causal Bayesian networks.
- We propose six mechanisms for lowering prediction error.
- We identify crucial conceptual, theoretical open problems in Predictive Processing.

## Predictive Processing vs. Predictive Coding

- Not **Friston-ese**, but **Clark-onian / Hohwy-esque**
- Focus on conceptual principle rather than Friston's "free-energy driven predictive coding" which is closely tied to the cortical hierarchy – we wish to abstract away from that and stay at Marr's computational level
- Computational translation of conceptual principles

## Predictive Processing & Marr's levels

<b>Computational level</b> Conceptual description	<b>Predictive Processing</b> [Clark, Hohwy] Keywords: predictions at various levels of detail, precision-weighted prediction errors, hypothesis updating, model revision
<b>Algorithmic level</b> Process-level description	<b>Predictive Coding</b> [Friston, Kilner, Spratling, Mathys] Keywords: low-level cognition, continuous Gaussian models, variational Bayes approximations, free-energy principle
<b>Implementational level</b> Neuronal level description	<b>Cortical microcircuits</b> [Bastos] Keywords: pyramid cells, feedforward-feedback connections, canonical microcircuits

## Predictive Processing & Marr's levels

<b>Computational level</b> Conceptual description	<b>Predictive Processing</b> [Clark, Hohwy] Keywords: predictions at various levels of detail, precision-weighted prediction errors, hypothesis updating, model revision
<b>Algorithmic level</b> Process-level description	<b>Belief Propagation</b> [Sanborn, Griffiths, Tenenbaum] Keywords: high-level cognition, structured discrete graphical models, sampling approximations, particle filtering
<b>Implementational level</b> Neuronal level description	<b>Networks of Spiking Neurons</b> [Maass, Lengyel, Hennequin] Keywords: Boltzmann machines, switching rate, noisy spikes

## Predictive Processing

### Brain as **prediction machine**

- *The brain continuously makes predictions about future sensory evidence based on its current best model of the causes of such evidence*

### **Bayesian Brain**

- *The brain combines prior knowledge with sensory evidence (from various sources) in a Bayesian way*

### **Hierarchical Brain**

- *The brain is organized in a hierarchical way, where "high level" information influences "low level" information and vice versa*

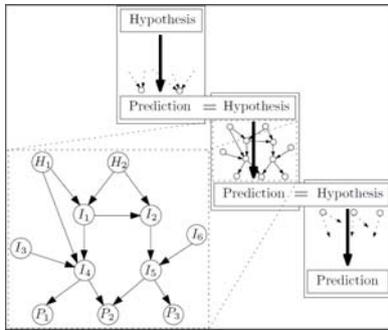

## Key sub-processes

- Making **predictions** of expected input based on the generative models
- Comparing predicted inputs with actual inputs and **computing prediction error**
- **Explaining away** prediction errors (minimizing prediction error)
- **Learning** and adapting generative models

## From conceptual idea to formal model

- Predictive processing is assumed to **explain and unify all of cognition**, including higher cognition
- To model, e.g., complex social interactions, Theory of Mind, intention recognition, and problem solving, we need rich enough knowledge structures to model dependences
  - We argue (Ostrowska et al., 2014) that simple Gaussian models are **not sufficiently rich** models for higher cognition
  - We propose to use **causal Bayesian networks** as knowledge structures instead to describe predictive processing

### Computational model – prediction generation

**Hypothesis**  
variables  
 $Hyp = \{H_1, H_2\}$

**Prediction**  
variables  
 $Pred = \{P_1, P_2\}$

**Intermediate**  
variables  
 $Int = \{I_1, \dots, I_6\}$

### Computational model – error estimation

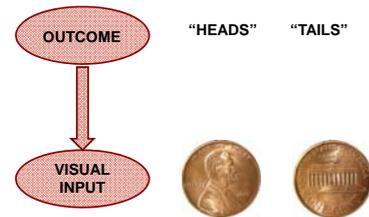

- Prediction and Observation are **probability distributions** over the prediction variables  $Pred$
- Prediction is defined as computing the **posterior distribution**  $Pr_{(Pred)}$  given the parameters in the network
- Prediction error is set difference  $Pr_{(Obs)} - Pr_{(Pred)}$
- Estimating the size of this error is defined as computing a KL-divergence or **relative entropy** between predicted distribution and observed distribution

$$D_{KL}(Pr_{(Obs)} || Pr_{(Pred)}) = \sum_{p \in \Omega(Pred)} Pr_{Obs}(p) \log \left( \frac{Pr_{Obs}(p)}{Pr_{Pred}(p)} \right)$$

### Precision of prediction & prediction error

- Precision** is a property of both a **prediction** and of a **prediction error**
- Precision of a prediction** describes how much uncertainty there is in a prediction (and consequently, how informative the actual observation of what was predicted will be)
- Precision of a prediction error** describes what proportion of this uncertainty can be attributed to inherent stochastic nature of the process that caused the outcome of the prediction → **precision-weighted prediction errors**

### Example: tossing coins

On the whiteboard!

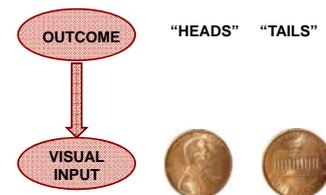

### Computational model – error minimization

- Prediction error minimization: "doing something" such that  $D_{KL}(Obs || Pred)$  is minimized
- Four possible ways of "doing something" (Kwisthout, van Rooij, & Bekkering, 2017):
  - Belief revision (revise hyp probability distribution)
  - Model revision (revise parameters in the CPTs)
  - Passive intervention (evidence gathering)
  - Active intervention (acting, i.e., setting variables)
- Each of them with the goal of lowering relative entropy
- We'll go through them

### Intuitive examples of lowering prediction error

- Belief revision** – in cases with 'expected uncertainty' where the world model is stable but there is information carried by the prediction error

- On the whiteboard!

### Intuitive examples of lowering prediction error

- **Model revision** – in cases with 'unexpected uncertainty' where the world model suddenly turns out to be misinformative
- Prediction errors can be dealt with by changing some of the **model parameters** (tuning) such that the model can better predict the observations
- E.g., your model about what constitutes a friendly greeting may need updating (for the 30+ people amongst us)

### Intuitive examples of lowering prediction error

- **Passive intervention** – reduce prediction error by reducing uncertainty in the world: **add** additional observations
- This is what we intuitively do when confronted with the "train effect": when you're sitting in a train that is standing still at the station and you are looking at an opposite train – who is moving?
- You'd probably look at a stationary point to reduce uncertainty (e.g., the railway station buildings)

### Intuitive examples of lowering prediction error

- **Active intervention** – reduce prediction error by actively intervening in the world (active inference): bring prediction and observation closer together by **changing** the observation
- This has been proposed as a means of coupling action and perception in a single framework, where motor acts are the result of a mismatch between a "predicted" (expected) state and the actual, perceived state of the world

### Next time: how to develop a generative model?
